

Day 5 Notes

First Real Project Scaffold – Using Antigravity

★ Today = big milestone! Moved from practice folders to the ACTUAL project repo. Used Antigravity (AI) for the first time to build real boilerplate.

1 Why Use Antigravity Today (and not before)?

Days 1-4 were hand-typed on purpose, to actually learn React/Express/SQL myself.

A project SCAFFOLD (folder setup, config files) is repetitive boilerplate, not a learning opportunity – perfect job for an AI coding agent instead.

Model used: Claude Sonnet 4.5 (Thinking) – good for careful, multi-file project setup.

2 The Prompt I Gave It

Told Antigravity: build ONLY the scaffold (no features yet), using React+Vite for /client,

Express+SQLite for /server, plus a README and .gitignore. Told it to explain its folder choices.

3 What It Generated

```
virtual_tryon/
├── client/           → React frontend (Vite)
│   ├── src/
│   │   ├── App.jsx
│   │   ├── main.jsx
│   │   └── index.css
│   ├── vite.config.js (has /api proxy → localhost:5000)
│   └── package.json
├── server/          → Express backend
│   ├── data/
│   │   └── store.db (auto-created, git-ignored)
│   ├── db.js        → sets up database + products table
│   ├── index.js     → Express app, CORS, routes
│   └── package.json
├── .gitignore       → excludes node_modules, .env, *.db
└── README.md
```

Nice touches it added: a proxy in vite.config.js (so client can call /api/products instead of the full URL), and separating db.js from index.js to keep database code and route code apart.

4 *Always Test Before Trusting AI Code*

Even though Antigravity wrote it, I didn't just assume it worked — I actually ran both pieces myself:

```
cd server
npm install
node index.js      → "Server running on http://localhost:5000"

cd client
npm install
npm run dev        → http://localhost:5173/
```

Checked in browser: saw "Virtual Try-On Store" heading, and localhost:5000/api/products showed an empty array [] (expected, since no data was seeded yet).

5 *Pushed the Real Scaffold*

```
git add .
git commit -m "Add project scaffold: client, server, db setup"
git push
```

This is now the real shared foundation — my friend will pull this down and build on top of it, instead of us each building separate copies.

6 *The Plan From Here*

- Me → try-on / AI feature (pose detection, overlay)
- Friend → e-commerce shell (product pages, cart, checkout)
- We'll each work on our own git branch, then merge together later

Big takeaway:

AI tools like Antigravity are great for repetitive boilerplate (folder setup, config), once I already understand the underlying concepts myself. Always TEST generated code before trusting or pushing it. From here, me and my friend build different features on the SAME shared scaffold, instead of separate projects.
